AI-Based Fake Identity & Document Screening System

Abstract

Identity fraud and document forgery have become major concerns for banks, government agencies, and online platforms, as manual verification methods struggle to keep pace with increasingly sophisticated fraud techniques. This project proposes an AI-Based Fake Identity and Document Screening System that uses machine learning and computer vision to automatically detect fraudulent documents and impersonation attempts.

The system uses Optical Character Recognition (OCR) to extract data from ID documents and cross-checks it against structured databases for consistency. Convolutional Neural Networks (CNNs) and image forensics techniques detect tampering, pixel-level anomalies, and signs of digital manipulation. Facial recognition and liveness detection modules compare the document photo with a live user capture, preventing spoofing through photo substitution or deepfakes. These checks feed into a multi-layered pipeline covering document authenticity, data validation, and facial similarity scoring.

Experimental evaluation demonstrates that the system achieves high accuracy in distinguishing authentic from fraudulent documents while maintaining low false-positive rates, making it suitable for deployment in banking, fintech, e-commerce, and government verification services. The paper concludes by discussing limitations, including adversarial attacks and dataset bias, and outlines directions for future work such as multi-modal liveness detection and cross-border document standardization.

This approach reduces manual review time and human error while improving fraud detection accuracy for KYC and online onboarding use cases.
